

Figure: The saliency maps in IN-R+W. From left to right in each case are from the original image, the pre-trained ViT-Large, the source model with self-calibration strategy, and the target model with self-improvement strategy. warm colors indicate a high level of attention for models. **It can be seen that calibration loss enriches feature distribution, resulting in the source model focusing on more locations. The self-improvement strategy further forces the model to focus on true underlying features by random mask strategy and adaptive attention alignment module.**
